Abstract

We study the charmful three-body baryonic B decays $\bar{B} \rightarrow D^{(*)}N\bar{N}$: the color-allowed modes $\bar{B}^0 \rightarrow D^{(*)+}n\bar{p}$ and the color-suppressed ones $\bar{B}^0 \rightarrow D^{(*)0}p\bar{p}$. While the D^{*+}/D^+ production ratio is predicted to be of order 3, it is found that $D^0p\bar{p}$ has a similar rate as $D^{*0}p\bar{p}$. It is pointed out that $\bar{B}^0 \rightarrow D(D^*)N\bar{N}$ are dominated by the nucleon vector current or by vector meson intermediate states, whereas $\bar{B}^0 \rightarrow D^0p\bar{p}$ proceeds mainly via the exchange of the axial-vector intermediate state $a_1(1260)$. The study of the $N\bar{N}$ invariant mass distribution in general indicates a threshold baryon pair production; that is, a recoil charmed meson accompanied by a low mass baryon pair except that the spectrum of $D^0p\bar{p}$ has a hump at large $p\bar{p}$ invariant mass $m_{p\bar{p}} \sim 3.0$ GeV.

I. INTRODUCTION

Previously CLEO has reported the first observation of color-allowed charmful baryonic B decays with sizable rates [1]:

$$\begin{aligned}\mathcal{B}(\overline{B}^0 \rightarrow D^{*+}n\bar{p}) &= (14.5_{-3.0}^{+3.4} \pm 2.7) \times 10^{-4}, \\ \mathcal{B}(\overline{B}^0 \rightarrow D^{*+}p\bar{p}\pi^-) &= (6.5_{-1.2}^{+1.3} \pm 1.0) \times 10^{-4}.\end{aligned}\tag{1}$$

This, when combining with the non-observation of the two-body baryonic B decays such as $B \rightarrow N\bar{N}$ [2], implies the dominance of multi-body final states in decays of B mesons into baryons. Recently, Belle announced a similar measurement for color-suppressed baryonic decay decays at the level of 10^{-4} [3]:

$$\begin{aligned}\mathcal{B}(\overline{B}^0 \rightarrow D^{*0}p\bar{p}) &= (1.20_{-0.29}^{+0.33} \pm 0.21) \times 10^{-4}, \\ \mathcal{B}(\overline{B}^0 \rightarrow D^0p\bar{p}) &= (1.18 \pm 0.15 \pm 0.16) \times 10^{-4},\end{aligned}\tag{2}$$

with 5.6σ and 12σ statistical significance respectively. Roughly speaking, the $D^{*0}p\bar{p}$ rate is smaller than that of $D^{*+}n\bar{p}$ by one order of magnitude.

Another class of charmful baryonic B decays is $\overline{B} \rightarrow \Lambda_c(\Sigma_c)\bar{N}X$. The early CLEO measurement [4] and the new Belle [5] and CLEO [6] results show that the three-body charmful decay $B^- \rightarrow \Lambda_c\bar{p}\pi^-$ has a magnitude larger than $\overline{B}^0 \rightarrow \Lambda_c\bar{p}$. These modes have been theoretically studied in [7]. The recent first observation of the penguin-dominated charmless baryonic decay $B^- \rightarrow p\bar{p}K^-$ by Belle [8] clearly indicates that it has a much larger rate than the two-body counterpart $\overline{B}^0 \rightarrow p\bar{p}$. Theoretically, it has been explained in [9] why some charmless three-body final states in which baryon-antibaryon pair production is accompanied by a meson have a rate larger than their two-body counterparts.

Under the factorization assumption, the decay amplitude, dominated by the color-allowed external W -emission, is proportional to $a_1\langle O_1 \rangle_{\text{fact}}$ where O_1 is a charged current–charged current 4-quark operator, while the decay amplitude, governed by the factorizable color-suppressed internal W -emission, is described by $a_2\langle O_2 \rangle_{\text{fact}}$ with O_2 being a neutral current–neutral current 4-quark operator. Since $\overline{B}^0 \rightarrow D^{(*)+}n\bar{p}$ are color-allowed, while $\overline{B}^0 \rightarrow D^{(*)+}p\bar{p}$ are color-suppressed, it is naively expected that the measured ratio $R = \Gamma(\overline{B}^0 \rightarrow D^{(*)0}p\bar{p})/\Gamma(\overline{B}^0 \rightarrow D^{(*)+}n\bar{p})$ can be used to extract the parameter $|a_2/a_1|$, just as in the case of $\overline{B}^0 \rightarrow D^0\pi^0$ and $\overline{B}^0 \rightarrow D^+\pi^-$ decays. However, there is one complication here: the factorizable decay amplitude of color-suppressed baryonic B decays $\overline{B}^0 \rightarrow D^{(*)0}p\bar{p}$ involves a three-body hadronic matrix element which is basically unknown. Therefore, one needs to impose further theoretical assumptions in order to extract a_2 from the color-suppressed baryonic B decay modes. The color-favored decays $\overline{B}^0 \rightarrow D^{(*)+}n\bar{p}$ have been studied in [11]. It turns out that D^{*+}/D^+ production ratio is predicted to be of order 3. It is thus anticipated that the D^{*0}/D^0 production ratio in color suppressed decays is also of order 3.

However, experimentally the latter is consistent with unitary. This motivates us to investigate why $D^0 p \bar{p}$ has a similar rate as $D^{*0} p \bar{p}$.

All $\bar{B} \rightarrow D^{(*)} N \bar{N}$ decays can be described in terms of the pole model; they receive contributions from various intermediate states: vector mesons such as ρ , ω , axial-vector mesons $a_1(1260)$, $f_1(1285)$, $f_1(1420)$, and pseudoscalar mesons π, η, η' . It appears that the decay $\bar{B}^0 \rightarrow D^0 p \bar{p}$ is very special: it is dominated by the axial-vector meson states, whereas the other modes proceed mainly through the vector meson poles. This enables us to explain the similar rates for $D^0 p \bar{p}$ and $D^{*0} p \bar{p}$.

This paper is organized as follows. We first discuss the color-favored modes $\bar{B}^0 \rightarrow D^{(*)+} n \bar{p}$ in Sec. 2 and then turn to the color-suppressed ones $\bar{B}^0 \rightarrow D^{(*)0} p \bar{p}$ in Sec. 3. Discussions and conclusions are presented in Sec. 4.

II. COLOR-ALLOWED $\bar{B}^0 \rightarrow D^{(*)+} n \bar{p}$

At the quark level, the color-allowed decays $\bar{B}^0 \rightarrow D^{(*)+} n \bar{p}$ proceed through the factorizable external W -emission and W -exchange diagrams, and the nonfactorizable internal W -emission [see Fig. 1(a)], while $\bar{B}^0 \rightarrow D^{0(*)} p \bar{p}$ via the factorizable internal W -emission, W -exchange diagrams and the nonfactorizable internal W -emission [see Fig. 2(a)]. More precisely, their factorizable amplitudes read

$$\begin{aligned} A(\bar{B}^0 \rightarrow D^{+(*)} n \bar{p})_{\text{fact}} &= \frac{G_F}{\sqrt{2}} V_{ud}^* V_{cb} \left\{ a_1 \langle n \bar{p} | (\bar{d}u) | 0 \rangle \langle D^{+(*)} | (\bar{c}b) | \bar{B}^0 \rangle \right. \\ &\quad \left. + a_2 \langle D^{+(*)} n \bar{p} | (\bar{c}u) | 0 \rangle \langle 0 | (\bar{d}b) | \bar{B}^0 \rangle \right\}, \\ A(\bar{B}^0 \rightarrow D^{0(*)} p \bar{p})_{\text{fact}} &= \frac{G_F}{\sqrt{2}} V_{ud}^* V_{cb} \left\{ a_2 \langle n \bar{p} | (\bar{d}b) | \bar{B}^0 \rangle \langle D^{0(*)} | (\bar{c}u) | 0 \rangle \right. \\ &\quad \left. + a_2 \langle D^{0(*)} p \bar{p} | (\bar{c}u) | 0 \rangle \langle 0 | (\bar{d}b) | \bar{B}^0 \rangle \right\}, \end{aligned} \quad (3)$$

where $(\bar{q}_1 q_2) \equiv \bar{q}_1 \gamma_\mu (1 - \gamma_5) q_2$, and a_1, a_2 , which will be specified later, are some renormalization scale and scheme independent parameters. The second term in each decay amplitude of Eq. (3) corresponds to the W -exchange amplitude, which is not only color but also helicity suppressed. Since the three-body matrix element $\langle n \bar{p} | (\bar{d}b) | \bar{B}^0 \rangle$ is basically unknown, we will evaluate the color-suppressed amplitude based on the pole model approximation.

Let us first focus on the decays $\bar{B}^0 \rightarrow D^{+(*)} n \bar{p}$. To evaluate their factorizable amplitude, we need to know various harmonic matrix elements. The one-body and two-body mesonic matrix elements are given by [10]

$$\begin{aligned} \langle P(q) | A_\mu | 0 \rangle &= -i f_P q_\mu, & \langle V(p, \varepsilon) | V_\mu | 0 \rangle &= f_V m_V \varepsilon_\mu^*, \\ \langle P(p) | V_\mu | B(p_B) \rangle &= \left(p_{B\mu} + p_\mu - \frac{m_B^2 - m_P^2}{q^2} q_\mu \right) F_1^{BP}(q^2) + \frac{m_B^2 - m_P^2}{q^2} q_\mu F_0^{BP}(q^2), \end{aligned}$$

FIG. 1. (a) Quark diagrams for $\bar{B}^0 \rightarrow D^+ n \bar{p}$ and (b) the pole diagram for the factorizable external W -emission.

$$\begin{aligned}
\langle V(p, \varepsilon) | (V - A)_\mu | B(p_B) \rangle = & \frac{2i}{m_B + m_V} \epsilon_{\mu\nu\alpha\beta} \varepsilon^{*\nu} p^\alpha p_B^\beta V^{BV}(q^2) - \left\{ (m_B + m_V) \varepsilon_\mu^* A_1^{BV}(q^2) \right. \\
& - \frac{\varepsilon^* \cdot p_B}{m_B + m_V} (p_B + p)_\mu A_2^{BV}(q^2) \\
& \left. - 2m_V \frac{\varepsilon^* \cdot p_B}{q^2} q_\mu [A_3^{BV}(q^2) - A_0^{BV}(q^2)] \right\}, \quad (4)
\end{aligned}$$

where $q = p_B - p$, $F_1(0) = F_0(0)$, $A_3(0) = A_0(0)$, and

$$A_3(q^2) = \frac{m_B + m_V}{2m_V} A_1(q^2) - \frac{m_B - m_V}{2m_V} A_2(q^2). \quad (5)$$

The two-body baryonic matrix element appearing in Eq. (3) can be parametrized as

$$\begin{aligned}
\langle n(p_n) \bar{p}(p_{\bar{p}}) | (V - A)_\mu | 0 \rangle = & \bar{u}_n(p_n) \left\{ f_1^{np}(q^2) \gamma_\mu + i \frac{f_2^{np}(q^2)}{2m_N} \sigma_{\mu\nu} q^\nu + \frac{f_3^{np}(q^2)}{2m_N} q_\mu \right. \\
& \left. - \left[g_1^{np}(q^2) \gamma_\mu + i \frac{g_2^{np}(q^2)}{2m_N} \sigma_{\mu\nu} q^\nu + \frac{g_3^{np}(q^2)}{2m_N} q_\mu \right] \gamma_5 \right\} v_{\bar{p}}(p_{\bar{p}}), \quad (6)
\end{aligned}$$

with $q = p_p + p_{\bar{p}}$. Among the six baryonic form factors, the vector form factor $f_3(q^2)$ vanishes because of conservation of vector current (CVC), while the absence of the second-class current implies $g_2(q^2) = 0$. Using CVC, the vector form factors $f_{1,2}(q^2)$ can be related to the electromagnetic form factors of the nucleon defined by

FIG. 2. (a) Quark diagrams for $\bar{B}^0 \rightarrow D^0 p \bar{p}$ and (b) the pole diagrams for the factorizable internal W -emission.

$$\langle N(p_1) \bar{N}(p_2) | J_\mu^{\text{em}} | 0 \rangle = \bar{u}_N(p_1) \left[F_1(q^2) \gamma_\mu + i \frac{F_2(q^2)}{2m_N} \sigma_{\mu\nu} q^\nu \right] v_{\bar{N}}(p_2). \quad (7)$$

Specifically (see e.g. [9]),

$$f_{1,2}^{np}(t) = F_{1,2}^p(t) - F_{1,2}^n(t), \quad (8)$$

where $t = q^2$.

The experimental data of the nucleon's e.m. form factors are customarily described in terms of the electric and magnetic Sachs form factors $G_E^N(t)$ and $G_M^N(t)$ which are related to F_1^N and F_2^N via

$$G_E^{p,n}(t) = F_1^{p,n}(t) + \frac{t}{4m_N^2} F_2^{p,n}(t), \quad G_M^{p,n}(t) = F_1^{p,n}(t) + F_2^{p,n}(t). \quad (9)$$

A recent phenomenological fit to the experimental data of nucleon form factors has been carried out in [11] using the following parametrization:

$$|G_M^p(t)| = \left(\frac{x_1}{t^2} + \frac{x_2}{t^3} + \frac{x_3}{t^4} + \frac{x_4}{t^5} + \frac{x_5}{t^6} \right) \left[\ln \frac{t}{Q_0^2} \right]^{-\gamma},$$

$$|G_M^n(t)| = \left(\frac{y_1}{t^2} + \frac{y_2}{t^3} \right) \left[\ln \frac{t}{Q_0^2} \right]^{-\gamma}, \quad (10)$$

where $Q_0 = \Lambda_{\text{QCD}} \approx 300$ MeV and $\gamma = 2 + \frac{4}{3\beta} = 2.148$. We will follow [12] to use the best fit values

$$\begin{aligned}
x_1 &= 420.96 \text{ GeV}^4, & x_2 &= -10485.50 \text{ GeV}^6, & x_3 &= 106390.97 \text{ GeV}^8, \\
x_4 &= -433916.61 \text{ GeV}^{10}, & x_5 &= 613780.15 \text{ GeV}^{12},
\end{aligned} \tag{11}$$

and

$$y_1 = 236.69 \text{ GeV}^4, \quad y_2 = -579.51 \text{ GeV}^6, \tag{12}$$

extracted from the neutron data under the assumption $|G_E^n| = |G_M^n|$. Note that the form factors given by Eq. (10) do satisfy the constraint from perturbative QCD in the limit of large t [11]. Also as stressed in [11], time-like magnetic form factors are expected to behave like space-like magnetic form factors, i.e. real and positive for the proton, but negative for the neutron.

In terms of the nucleon magnetic and electric form factors, the weak form factors read

$$\begin{aligned}
f_1^{np}(t) &= \frac{\frac{t}{4m_N^2} G_M^p(t) - G_E^p(t)}{t/(4m_N^2) - 1} - \frac{\frac{t}{4m_N^2} G_M^n(t) - G_E^n(t)}{t/(4m_N^2) - 1}, \\
f_2^{np}(t) &= -\frac{G_M^p(t) - G_E^p(t)}{t/(4m_N^2) - 1} + \frac{G_M^n(t) - G_E^n(t)}{t/(4m_N^2) - 1}.
\end{aligned} \tag{13}$$

According to perturbative QCD, the weak form factors in the large t limit have the asymptotic expressions [13]

$$f_1^{np}(t) \rightarrow G_M^p(t) - G_M^n(t), \quad g_1^{np}(t) \rightarrow \frac{5}{3} G_M^p(t) + G_M^n(t). \tag{14}$$

It is easily seen that this is consistent with the large t behavior of f_1^{np} given by Eq. (13).

For the axial form factor $g_1(t)$, we shall follow [14] to assume that it has a similar expression as $G_M^n(t)$

$$g_1^{np}(t) = \left(\frac{d_1}{t^2} + \frac{d_2}{t^3} \right) \left[\ln \frac{t}{Q_0^2} \right]^{-\gamma}, \tag{15}$$

where the coefficient d_1 is related to x_1 and y_1 by considering the asymptotic behavior of Sachs form factors G_M^p and G_M^n [see Eq. (10)]

$$d_1 = \frac{5}{3} x_1 - y_1. \tag{16}$$

As shown in [9], the induced pseudoscalar form factor g_3 corresponds to a pion pole contribution to the $n\bar{p}$ axial matrix element and it has the form

$$g_3^{np}(t) = -\frac{4m_N^2}{t - m_\pi^2} g_1^{np}(t). \tag{17}$$

III. COLOR-SUPPRESSED $\bar{B}^0 \rightarrow D^{(*)0} p \bar{p}$

We next turn to the color-suppressed modes $\bar{B}^0 \rightarrow D^{(*)0} p \bar{p}$ and assume that the main contributions arise from the factorizable internal W -emission diagram [see Fig. 2(a)]. There are two corresponding pole diagrams as depicted in Fig. 2(b): one with bottom baryon poles $\Sigma_b(\frac{1}{2}^+)$ and $\Sigma_b^*(\frac{1}{2}^-)$, and the other with meson poles. The low-lying meson intermediate states are: $\pi^0, \eta, \eta', \rho^0, \omega$, and a_1^0 and possibly $f_1(1285)$ and $f_1(1420)$.

A. Meson pole contributions

The meson pole contribution from Fig. 2 (b) is

$$\begin{aligned}
A(\bar{B}^0 \rightarrow D^0 p \bar{p})_{\mathcal{M}} = & \frac{G_F}{\sqrt{2}} V_{ud}^* V_{cb} a_2 \langle D^0 | (\bar{c}u) | 0 \rangle \left\{ - \left[\langle \pi^0 | (\bar{d}b) | \bar{B}^0 \rangle \frac{i}{q^2 - m_\pi^2} g_{\pi NN} \right. \right. \\
& + \langle \eta | (\bar{d}b) | \bar{B}^0 \rangle \frac{i}{q^2 - m_\eta^2} g_{\eta NN} + \langle \eta' | (\bar{d}b) | \bar{B}^0 \rangle \frac{i}{q^2 - m_{\eta'}^2} g_{\eta' NN} \left. \right] \bar{u}_p \gamma_5 v_{\bar{p}} \\
& + \langle \rho^0 | (\bar{d}b) | \bar{B}^0 \rangle \frac{i}{q^2 - m_\rho^2} \bar{u}_p \varepsilon_\rho^\nu \left(g_1^{\rho NN} \gamma_\nu + i \frac{g_2^{\rho NN}}{2m_N} \sigma_{\nu\lambda} q^\lambda \right) v_{\bar{p}} \\
& + \langle \omega | (\bar{d}b) | \bar{B}^0 \rangle \frac{i}{q^2 - m_\omega^2} \bar{u}_p \varepsilon_\omega^\nu \left(g_1^{\omega NN} \gamma_\nu + i \frac{g_2^{\omega NN}}{2m_N} \sigma_{\nu\lambda} q^\lambda \right) v_{\bar{p}} \\
& \left. + \langle a_1^0 | (\bar{d}b) | \bar{B}^0 \rangle \frac{i}{q^2 - m_{a_1}^2} g_1^{a_1 NN} \bar{u}_p \not{\epsilon}_{a_1} \gamma_5 v_{\bar{p}} \right\}, \tag{18}
\end{aligned}$$

where $q = p_B - p_D = p_p + p_{\bar{p}}$. For simplicity, we have concentrated on the low-lying poles and neglected those contributions from the higher axial vector meson states such as $f_1(1285)$ and $f_1(1420)$. As we shall see, the vector and tensor coupling constants $g_1^{\rho NN}$ and $g_2^{\rho NN}$ are related to the vector form factors f_1^{np} and f_2^{np} respectively, while $g_1^{a_1 NN}$ and $g_{\pi NN}$ are connected to the axial-vector form factors g_1^{np} and g_3^{np} respectively.

After some manipulation we obtain

$$\begin{aligned}
A(\bar{B}^0 \rightarrow D^0 p \bar{p})_{\mathcal{M}} = & -\frac{G_F}{\sqrt{2}} V_{ud}^* V_{cb} f_D a_2 \left\{ \left[\frac{1}{\sqrt{2}} (m_B^2 - m_\pi^2) F_0^{B\pi}(m_D^2) \frac{g_{\pi NN}}{q^2 - m_\pi^2} \right. \right. \\
& + (m_B^2 - m_\eta^2) F_0^{B\eta}(m_D^2) \frac{g_{\eta NN}}{q^2 - m_\eta^2} + (m_B^2 - m_{\eta'}^2) F_0^{B\eta'}(m_D^2) \frac{g_{\eta' NN}}{q^2 - m_{\eta'}^2} \left. \right] \bar{u}_p \gamma_5 v_{\bar{p}} \\
& + \frac{\sqrt{2} m_\rho}{q^2 - m_\rho^2} A_0^{B\rho}(m_D^2) \bar{u}_p \left[- (g_1^{\rho NN} + g_2^{\rho NN}) \not{p}_B + \frac{g_2^{\rho NN}}{2m_N} (p_p - p_{\bar{p}}) \cdot p_B \right] v_{\bar{p}} \\
& + \frac{2m_\omega}{q^2 - m_\omega^2} A_0^{B\omega}(m_D^2) \bar{u}_p \left[- (g_1^{\omega NN} + g_2^{\omega NN}) \not{p}_B + \frac{g_2^{\omega NN}}{2m_N} (p_p - p_{\bar{p}}) \cdot p_B \right] v_{\bar{p}} \\
& \left. + \frac{\sqrt{2} m_{a_1}}{q^2 - m_{a_1}^2} V_0^{Ba_1}(m_D^2) g_1^{a_1 NN} \bar{u}_p \left[- \not{p}_B + \frac{p_B \cdot q \not{q}}{m_{a_1}^2} \right] \gamma_5 v_{\bar{p}} \right\}, \tag{19}
\end{aligned}$$

where we have applied the relations $\bar{u}_p \not{p} v_{\bar{p}} = 0$, $(p_p - p_{\bar{p}}) \cdot q = 0$ and employed the form factors defined by

$$\begin{aligned} \langle a_1^-(p_{a_1}) | (\bar{u}b)_{V-A} | \bar{B}^0(p_B) \rangle &= \frac{2i}{m_B + m_{a_1}} \epsilon_{\mu\nu\alpha\beta} \varepsilon^{*\nu} p_{a_1}^\alpha p_B^\beta A^{Ba_1}(q^2) \\ &\quad - \left\{ (m_B + m_{a_1}) \varepsilon_\mu^* V_1^{Ba_1}(q^2) - \frac{\varepsilon^* \cdot p_B}{m_B + m_{a_1}} (p_B + p_{a_1})_\mu V_2^{Ba_1}(q^2) \right. \\ &\quad \left. - 2m_{a_1} \frac{\varepsilon^* \cdot p_B}{q^2} q_\mu [V_3^{Ba_1}(q^2) - V_0^{Ba_1}(q^2)] \right\}, \end{aligned} \quad (20)$$

with

$$V_3(q^2) = \frac{m_B + m_V}{2m_V} V_1(q^2) - \frac{m_B - m_V}{2m_V} V_2(q^2), \quad (21)$$

and $V_3(0) = V_0(0)$. Note that the pion in the form factor $F_0^{B\pi}$ is referred to the charged one, so are the form factors $A_0^{B\rho}$ and $V_0^{Ba_1}$.

Likewise, the meson pole contribution to $\bar{B}^0 \rightarrow D^{*0} p \bar{p}$ reads

$$\begin{aligned} A(\bar{B}^0 \rightarrow D^{*0} p \bar{p})_{\mathcal{M}} &= \frac{G_F}{\sqrt{2}} V_{ud}^* V_{cb} a_2 f_{D^*} m_{D^*} \left\{ \left[\sqrt{2} F_1^{B\pi}(m_{D^*}^2) \frac{g_{\pi NN}}{q^2 - m_\pi^2} \right. \right. \\ &\quad \left. + 2 F_1^{B\eta}(m_{D^*}^2) \frac{g_{\eta NN}}{q^2 - m_\eta^2} + 2 F_1^{B\eta'}(m_{D^*}^2) \frac{g_{\eta' NN}}{q^2 - m_{\eta'}^2} \right] (\varepsilon_{D^*}^* \cdot p_B) \bar{u}_p \gamma_5 v_{\bar{p}} \\ &\quad + \langle \rho^0 | \bar{d} \not{\varepsilon}_{D^*}^* (1 - \gamma_5) b | \bar{B}^0 \rangle \frac{1}{q^2 - m_\rho^2} \bar{u}_p \varepsilon_\rho^\mu (g_1^{\rho NN} \gamma_\mu + i \frac{g_2^{\rho NN}}{2m_N} \sigma_{\mu\nu} q^\nu) v_{\bar{p}} \\ &\quad + \langle \omega | \bar{d} \not{\varepsilon}_{D^*}^* (1 - \gamma_5) b | \bar{B}^0 \rangle \frac{1}{q^2 - m_\omega^2} \bar{u}_p \varepsilon_\omega^\mu (g_1^{\omega NN} \gamma_\mu + i \frac{g_2^{\omega NN}}{2m_N} \sigma_{\mu\nu} q^\nu) v_{\bar{p}} \\ &\quad \left. + \langle a_1^0 | \bar{d} \not{\varepsilon}_{D^*}^* (1 - \gamma_5) b | \bar{B}^0 \rangle \frac{1}{q^2 - m_{a_1}^2} \bar{u}_p (g_1^{a_1 NN} \not{\varepsilon}_{a_1} \gamma_5) v_{\bar{p}} \right\}. \end{aligned} \quad (22)$$

B. Baryon pole contributions

In addition to the aforementioned meson pole contributions, there also exist baryon pole diagrams, namely, the strong process $\bar{B}^0 \rightarrow \Sigma_b^{+(*)} \bar{p}$ followed by the weak decay $\Sigma_b^{+(*)} \rightarrow D^0 p$. Due to the large theoretical uncertainties with the $\frac{1}{2}^-$ state Σ_b^{+*} , we will focus on the $\frac{1}{2}^+$ intermediate state and its amplitude is given by

$$\begin{aligned} A(\bar{B}^0 \rightarrow D^0 p \bar{p})_{\mathcal{B}} &= \frac{G_F}{\sqrt{2}} V_{ud}^* V_{cb} f_D a_2 g_{\Sigma_b^+ \rightarrow B \bar{p}} \frac{1}{(p_p + p_D)^2 - m_{\Sigma_b}^2} \\ &\quad \times \bar{u}_p \left\{ f_1^{\Sigma_b^+ p}(m_D^2) [2p_D \cdot p_p + \not{p}_D (m_{\Sigma_b} - m_p)] \gamma_5 \right. \\ &\quad \left. + g_1^{\Sigma_b^+ p}(m_D^2) [2p_D \cdot p_p - \not{p}_D (m_{\Sigma_b} + m_p)] \right\} v_{\bar{p}}, \end{aligned} \quad (23)$$

where we have applied the factorization approximation to the weak decay $\Sigma_b^+ \rightarrow D^0 p$. Similarly, for $\bar{B}^0 \rightarrow D^{*0} p \bar{p}$ we have

$$\begin{aligned}
A(\bar{B}^0 \rightarrow D^{*0} p \bar{p})_{\mathcal{B}} &= \frac{G_F}{\sqrt{2}} V_{cb} V_{ud}^* f_{D^*} m_{D^*} a_2 g_{\Sigma_b^+ \rightarrow B \bar{p}} \frac{1}{(p_p + p_{D^*})^2 - m_{\Sigma_b}^2} \\
&\times \bar{u}_p \varepsilon^{*\mu} \left\{ f_1^{\Sigma_b^+ p}(m_{D^*}^2) [2p_{p\mu} + (m_{\Sigma_b} - m_p) \gamma_\mu + \gamma_\mu \not{p}_D] \gamma_5 \right. \\
&\left. + g_1^{\Sigma_b^+ p}(m_{D^*}^2) [2p_{p\mu} - (m_{\Sigma_b} + m_p) \gamma_\mu + \gamma_\mu \not{p}_D] \right\} v_{\bar{p}}, \tag{24}
\end{aligned}$$

where ε_μ^* is the polarization vector of the D^* .

The baryon pole contribution is expected to be suppressed relative to the meson pole due to the smallness of the strong coupling of $\Sigma_b^+ \rightarrow B^0 \bar{p}$ [9].

IV. CALCULATIONS AND RESULTS

To proceed numerical calculations we first need to know the relevant form factors, decay constants, strong couplings, and the parameters a_1, a_2 , which will be discussed in more detail below.

A. form factors and decay constants

For the mesonic form factors of $B \rightarrow P$ and $B \rightarrow V$ transitions we use the Melikhov-Stech (MS) model based on the constituent quark picture [15] and the Neubert-Rieckert-Stech-Xu (NRSX) model [16] which takes the Bauer-Stech-Wirbel (BSW) model [10] results for the form factors at zero momentum transfer but makes a different ansatz for their q^2 dependence, namely, a dipole behavior is assumed for the form factors F_1, A_0, A_2, V , motivated by heavy quark symmetry, and a monopole dependence for F_0, A_1 .

For $B \rightarrow a_1$ form factors, there are two existing calculations: one in a quark-meson model [17] and the other based on the QCD sum rule [18]. The results are quite different, for example, $V^{Ba_1}(0)$ computed in the quark-meson model, 1.20, is larger than the sum-rule prediction, -0.23 ± 0.05 , by a factor of five. We shall see later that $\bar{B}^0 \rightarrow D^0 p \bar{p}$ is rather sensitive to the form factor $V_0^{Ba_1}$. It turns that in order to accommodate the measurement of this decay, this form factor should be around 0.86 which is between the above-mentioned model calculations. In the present paper we shall use the quark-meson model results for the $B \rightarrow a_1$ form factors except that the value of $V_0^{Ba_1}(0)$ is replaced by 0.85 rather than 1.20.

To compute the form factors for $F_0^{B\eta}$ and $F_0^{B\eta'}$, it is more natural to consider the flavor basis of η_q and η_s defined by

$$\eta_q = \frac{1}{\sqrt{2}}(u\bar{u} + d\bar{d}), \quad \eta_s = s\bar{s}. \tag{25}$$

The wave functions of the η and η' are given by

$$\begin{pmatrix} \eta \\ \eta' \end{pmatrix} = \begin{pmatrix} \cos \phi & -\sin \phi \\ \sin \phi & \cos \phi \end{pmatrix} \begin{pmatrix} \eta_q \\ \eta_s \end{pmatrix}, \quad (26)$$

where $\phi = \theta + \arctan\sqrt{2}$, and θ is the η - η' mixing angle in the octet-singlet basis. The physical form factors then have the simple expressions:

$$F_{0,1}^{B\eta} = \frac{1}{\sqrt{2}} \cos \phi F_{0,1}^{B\eta_{u\bar{u}}}, \quad F_{0,1}^{B\eta'} = \frac{1}{\sqrt{2}} \sin \phi F_{0,1}^{B\eta'_{u\bar{u}}}. \quad (27)$$

Using $F_0^{B\eta_{u\bar{u}}}(0) = 0.307$ and $F_0^{B\eta'_{u\bar{u}}}(0) = 0.254$ obtained from [10] and the mixing angle $\phi = 39.3^\circ$ (or $\theta = -15.4^\circ$) [19] we find $F_0^{B\eta}(0) = 0.168$ and $F_0^{B\eta'}(0) = 0.114$ in the BSW model and hence the NRSX model. For other form-factor models, we shall apply the relation based on the isospin-quartet symmetry

$$F_{0,1}^{B\eta_{u\bar{u}}} = F_{0,1}^{B\eta'_{u\bar{u}}} = F_{0,1}^{B\pi} \quad (28)$$

and Eq. (27) to obtain the physical $B \rightarrow \eta$ and $B \rightarrow \eta'$ transition form factors. For the MS model we obtain $F_0^{B\eta}(0) = 0.141$ and $F_0^{B\eta'}(0) = 0.115$.

For the heavy-light baryonic form factors $f_1^{\Sigma_b^+ p}$ and $g_1^{\Sigma_b^+ p}$, we will follow [20] to apply the nonrelativistic quark model to evaluate the weak current-induced baryon form factors at zero recoil in the rest frame of the heavy parent baryon, where the quark model is most trustworthy. Following [21] we have

$$f_1^{\Sigma_b^+ p}(q_m^2) = 1.703, \quad g_1^{\Sigma_b^+ p}(q_m^2) = -0.166 \quad (29)$$

at zero recoil $q_m^2 = (m_{\Sigma_b} - m_p)^2$. Since the calculation for the q^2 dependence of form factors is beyond the scope of the non-relativistic quark model, we will follow the conventional practice to assume a pole dominance for the form-factor q^2 behavior:

$$f(q^2) = f(q_m^2) \left(\frac{1 - q_m^2/m_V^2}{1 - q^2/m_V^2} \right)^n, \quad g(q^2) = g(q_m^2) \left(\frac{1 - q_m^2/m_A^2}{1 - q^2/m_A^2} \right)^n, \quad (30)$$

where m_V (m_A) is the pole mass of the vector (axial-vector) meson with the same quantum number as the current under consideration.

For the decay constants we use $f_D = 200$ MeV, $f_{D^*} = 230$ MeV and $f_{a_1} = 205$ MeV.

B. strong couplings

In order to compute the decay rate for $\bar{B}^0 \rightarrow D^{(*)0} p \bar{p}$ we also need to know the strong couplings $g_{\pi NN}$, $g_1^{\rho NN}$, $g_2^{\rho NN}$ and $g_1^{a_1 NN}$ and their q^2 dependence. To do this, let us consider the pole contributions to $\bar{B}^0 \rightarrow D^{(*)+} n \bar{p}$. In the pole model description, the relevant

intermediate states are π^- , ρ^- and $a_1^-(1260)$ as shown in Fig. 1(b). The matrix element $\langle n\bar{p}|(V-A)_\mu|0\rangle$ then reads

$$\begin{aligned} \langle n\bar{p}|(V-A)_\mu|0\rangle_{\text{pole}} = & \bar{u}_n \left\{ \frac{\sqrt{2}f_\rho m_\rho}{q^2 - m_\rho^2} \left[g_1^{\rho NN} \gamma_\mu + i \frac{g_2^{\rho NN}}{2m_N} \sigma_{\mu\nu} q^\nu \right] \right. \\ & \left. - \frac{\sqrt{2}f_{a_1} m_{a_1}}{q^2 - m_{a_1}^2} g_1^{a_1 NN} \gamma_\mu \gamma_5 - \frac{\sqrt{2}f_\pi g_{\pi NN}}{q^2 - m_\pi^2} q_\mu \gamma_5 \right\} v_{\bar{p}}. \end{aligned} \quad (31)$$

Comparing this with Eq. (6) we see that the ρ^- meson is responsible for the vector form factors f_1 and f_2 , $a_1^-(1260)$ for g_1 and g_2 , and π^- for the induced pseudoscalar form factor g_3 . More precisely,

$$\begin{aligned} g_1^{\rho NN}(q^2) &= \frac{q^2 - m_\rho^2}{\sqrt{2}f_\rho m_\rho} f_1^{np}(q^2), & g_2^{\rho NN}(q^2) &= \frac{q^2 - m_\rho^2}{\sqrt{2}f_\rho m_\rho} f_2^{np}(q^2), \\ g_1^{a_1 NN}(q^2) &= \frac{q^2 - m_{a_1}^2}{\sqrt{2}f_{a_1} m_{a_1}} g_1^{np}(q^2), & g_{\pi NN}(q^2) &= \frac{(q^2 - m_\pi^2)}{2\sqrt{2}f_\pi m_N} g_3^{np}(q^2). \end{aligned} \quad (32)$$

As for the vector and tensor couplings of the ω meson, *a priori* they are not necessarily related to those of the ρ meson. For simplicity we shall assume that $g_{1,2}^{\omega NN}(q^2) = g_{1,2}^{\rho NN}(q^2)/\sqrt{2}$, noting that the ρ meson here is referred to the charged one.

As for the strong η and η' couplings with nucleons, we shall apply the 3P_0 quark-pair creation model [22,23] to estimate its strength relative to the pion. This model in which the $q\bar{q}$ pair is created from the vacuum with vacuum quantum numbers 3P_0 implies

$$\frac{g_{\eta p\bar{p}}}{g_{\pi p\bar{p}}} = \frac{\langle \Phi_{p^\uparrow}(124)\Phi_\eta(35)|\Phi_{p^\uparrow}(123)\Phi_{\text{vac}}(45)\rangle}{\langle \Phi_{p^\uparrow}(124)\Phi_{\pi^0}(35)|\Phi_{p^\uparrow}(123)\Phi_{\text{vac}}(45)\rangle}, \quad (33)$$

where the Φ 's are the spin-flavor wave functions and the vacuum wave function has the expression

$$\Phi_{\text{vac}} = \frac{1}{\sqrt{3}}(u\bar{u} + d\bar{d} + s\bar{s}) \otimes \frac{1}{\sqrt{2}}(\uparrow\downarrow + \downarrow\uparrow). \quad (34)$$

Using the proton wave function

$$p^\uparrow = \frac{1}{\sqrt{3}}[duu\chi_s + (12) + (13)], \quad (35)$$

with $abc\chi_s = (2a^\downarrow b^\uparrow c^\uparrow - a^\uparrow b^\downarrow c^\downarrow - a^\uparrow b^\downarrow c^\uparrow)/\sqrt{6}$, the π^0 meson wave function

$$\Phi_{\pi^0} = \frac{1}{\sqrt{2}}(u\bar{u} - d\bar{d}) \otimes \frac{1}{\sqrt{2}}(\uparrow\downarrow - \downarrow\uparrow), \quad (36)$$

and the η and η' flavor wave functions given by Eq. (26), we obtain

$$\frac{g_{\eta NN}}{g_{\pi NN}} = \frac{3}{5} \cos \phi, \quad \frac{g_{\eta' NN}}{g_{\pi NN}} = \frac{3}{5} \sin \phi. \quad (37)$$

Strictly speaking, the above relations hold only at low energies. But we shall assume their validity at arbitrary q^2 .

As for the strong coupling $g_{\Sigma_b^+ \rightarrow \bar{B}^0 p}$, we use the experimental result for $B^- \rightarrow \Lambda_c \bar{p} \pi^-$ to fix the absolute coupling strength of $g_{\Lambda_b^+ \rightarrow \bar{B}^0 p}$ which is in turn related to $g_{\Sigma_b^+ \rightarrow \bar{B}^0 p}$ via the 3P_0 quark-pair-creation model [7]. It is found that $|g_{\Sigma_b^+ \rightarrow \bar{B}^0 p}| \sim 5$.

C. a_1 and a_2

In the naive factorization approach, the parameters a_1 and a_2 are given by $a_{1,2} = c_{2,1} + c_{1,2}/N_c$, but this does not include nonfactorizable effects which are especially important for a_2 . Phenomenologically, one can treat $a_{1,2}$ as free parameters and extract them from experiment. The experimental measurement of $B \rightarrow J/\psi K$ leads to $|a_2(J/\psi K)| = 0.26 \pm 0.02$ [24]. This seems to be also supported by the study of $B \rightarrow D\pi$ decays: Assuming no relative phase between a_1 and a_2 , the result $a_2 \sim \mathcal{O}(0.20 - 0.30)$ [24,25] is inferred from the data of $\bar{B}^0 \rightarrow D^{(*)+} \pi^-$ and $B^- \rightarrow D^{(*)0} \pi^-$. However, the above value of a_2 leads to too small decay rates for $\bar{B}^0 \rightarrow D^{(*)0} \pi^0$ when compared to recent measurements by Belle and CLEO [26]. In order to account for the observation, one needs a larger $a_2(D\pi)$ with a non-trivial phase relative to a_1 [27–29].

Using the measurements of CLEO and Belle for $\bar{B}^0 \rightarrow D^{(*)0} \pi^0$ [26], the magnitudes of a_1 and a_2 and their relative phase are extracted in [28], as exhibited in Table I. We will use the values of $a_{1,2}(D\pi)$ to compute the decay rate for $\bar{B}^0 \rightarrow D^+ n \bar{p}$, $D^0 p \bar{p}$ and $a_{1,2}(D^* \pi)$ for $\bar{B}^0 \rightarrow D^{*+} n \bar{p}$, $D^{*0} p \bar{p}$.

TABLE I. Extraction of the parameters a_1 and a_2 from the measured $B \rightarrow D^{(*)} \pi$ rates by assuming a negligible W -exchange contribution. Note that $a_2(D\pi)$ and $a_2(D^* \pi)$ should be multiplied by a factor of $(200 \text{ MeV}/f_D)$ and $(230 \text{ MeV}/f_{D^*})$, respectively. This table is taken from [28].

Model	$ a_1(D\pi) $	$ a_2(D\pi) $	$a_2(D\pi)/a_1(D\pi)$	$ a_1(D^* \pi) $	$ a_2(D^* \pi) $	$a_2(D^* \pi)/a_1(D^* \pi)$
NRSX	0.85 ± 0.06	0.40 ± 0.05	$(0.47 \pm 0.05) \exp(i59^\circ)$	0.94 ± 0.04	0.31 ± 0.04	$(0.33 \pm 0.04) \exp(i63^\circ)$
MS	0.88 ± 0.06	0.47 ± 0.06	$(0.53 \pm 0.06) \exp(i59^\circ)$	0.85 ± 0.03	0.39 ± 0.05	$(0.46 \pm 0.06) \exp(i63^\circ)$

D. Results

In principle, the unknown parameter d_2 appearing in the form factor $g_1^{np}(q^2)$ [cf. Eq. (15)] can be fitted to the measured central value of the branching ratio for $\bar{B}^0 \rightarrow D^{*+} n \bar{p}$ as it is theoretically much more clean. However, we find that the decay rate of $\bar{B}^0 \rightarrow D^0 p \bar{p}$ is dominated by the axial-vector meson poles and hence it is rather sensitive to $g_1^{np}(t)$ and hence d_2 . Therefore, we instead fix it by fitting to the measured central value of $\mathcal{B}(\bar{B}^0 \rightarrow$

$D^0 p \bar{p}) = 1.18 \times 10^{-4}$. We obtain $d_2 = -2070 \text{ GeV}^6$ and -2370 GeV^6 , respectively, in NRSX and MS form-factor models.

The total decay rate for the process $\bar{B}(p_B) \rightarrow N(p_1) + \bar{N}(p_2) + D(p_3)$ is computed by the formula

$$\Gamma = \frac{1}{(2\pi)^3} \frac{1}{32m_B^3} \int |A|^2 dm_{12}^2 dm_{23}^2, \quad (38)$$

where $m_{ij}^2 = (p_i + p_j)^2$ with $p_3 = p_D$. To compute the branching ratios, we use the B meson lifetimes quoted in [30].

TABLE II. Branching ratios (in units of 10^{-4}) for charmful decays $\bar{B}^0 \rightarrow D^{(*)+} n \bar{p}$ and $\bar{B}^0 \rightarrow D^{(*)0} p \bar{p}$ calculated in the MS and NRSX form-factor models. The first (second) number in parentheses is the branching ratio due to the vector (axial-vector and pseudoscalar) current or intermediate vector (axial-vector) meson contributions.

Decay	MS	NRSX	Expt. [1,3]
$\bar{B}^0 \rightarrow D^+ n \bar{p}$	3.17 (3.04, 0.12)	3.64 (3.47, 0.16)	
$\bar{B}^0 \rightarrow D^{*+} n \bar{p}$	10.0 (9.54, 0.49)	11.0 (10.2, 0.76)	$14.5_{-3.0}^{+3.4} \pm 2.7$
$\bar{B}^0 \rightarrow D^0 p \bar{p}$	1.18 (0.15, 1.03)	1.17 (0.11, 1.06)	$1.18 \pm 0.15 \pm 0.16$
$\bar{B}^0 \rightarrow D^{*0} p \bar{p}$	1.58 (1.42, 0.17)	1.23 (1.12, 0.11)	$1.20_{-0.29}^{+0.33} \pm 0.21$

The results are shown in Table II. As stated before, we fit the unknown parameter d_2 to the measured branching ratio of $\bar{B}^0 \rightarrow D^0 p \bar{p}$ and then in turn predict other neutral baryonic B modes. The baryon pole contributions to $D^{(*)0} p \bar{p}$ are found to be at most of order of 10^{-6} and hence they are negligible. It is clear from Table II that the predicted rates are consistent with experiment. We see that $\bar{B}^0 \rightarrow D(D^*) N \bar{N}$ are dominated by the vector current or by vector meson intermediate states,* whereas $\bar{B}^0 \rightarrow D^0 p \bar{p}$ is dominated by the axial-vector intermediate state $a_1(1260)$. Note that the ratio D^{*+}/D^+ is of order 3, while D^{*0}/D^0 is close to unity.

In Fig. 3 we show the $n \bar{p}$ invariant mass distributions $d\mathcal{B}/dm_{n\bar{p}}$ of $\bar{B}^0 \rightarrow D^{*+} n \bar{p}$ and $\bar{B}^0 \rightarrow D^+ n \bar{p}$, where $m_{n\bar{p}}$ is the invariant mass of the nucleon pair. Evidently, the spectrum peaks at $m_{p\bar{p}} \sim 2.1 \text{ GeV}$, indicating a threshold enhancement for baryon production, that

As far as the axial vector contribution to the branching ratio is concerned, our result for $\bar{B}^0 \rightarrow D^{+} n \bar{p}$ is quite different from that given in [14], though the value of d_2 is similar. For example, $\mathcal{B}_A \sim 12.7 \times 10^{-4}$ is obtained in [14], whereas it is only 0.6×10^{-4} in our case. If g_1^{np} is identified with the asymptotic form $\frac{5}{3}G_M^p + G_M^n$ in the whole time-like region [cf. Eq.(14)], $\mathcal{B}_A$ in our case will be of order only 8×10^{-6} , while it can be as large as 1×10^{-4} in [14].

FIG. 3. The $n\bar{p}$ invariant mass distribution $d\mathcal{B}/dm_{n\bar{p}}$ of (a) $\bar{B}^0 \rightarrow D^{*+}n\bar{p}$ and (b) $\bar{B}^0 \rightarrow D^+n\bar{p}$.

is, a recoil charmed meson is accompanied by a nucleon pair with low invariant mass. This effect is due to the suppression of the baryonic form factors at large t . Physically, this can be visualized that the quark and anti-quark forming a nucleon pair are moving collinearly and energetically, so that the invariant mass $m_{p\bar{p}}$ tends to be small and near threshold.

Also shown in Fig. 4 are the $p\bar{p}$ invariant mass distributions of $\bar{B}^0 \rightarrow D^{*0}p\bar{p}$ and $\bar{B}^0 \rightarrow D^0p\bar{p}$ calculated in the MS model. It is clear that the spectrum of $D^{*0}p\bar{p}$ is similar to that of $D^{(*)+}n\bar{p}$. As for the differential rate of $D^0p\bar{p}$, it has a hump around $m_{p\bar{p}} \sim 3.0$ GeV, which is caused by the mass term $q^\mu q^\nu / m_{a_1}^2$ in the propagator of the a_1 meson.[†] We see that the predicted spectrum is consistent with experiment.

V. CONCLUSIONS

We have studied the charmful three-body baryonic B decays $\bar{B} \rightarrow D^{(*)}N\bar{N}$: the color-allowed modes $\bar{B}^0 \rightarrow D^{(*)+}n\bar{p}$ and the color-suppressed ones $\bar{B}^0 \rightarrow D^{(*)0}p\bar{p}$. While the D^{*+}/D^+ production ratio is predicted to be of order 3, it is found that $D^0p\bar{p}$ has a similar rate as $D^{*0}p\bar{p}$. It is pointed out that $\bar{B}^0 \rightarrow D(D^*)N\bar{N}$ are dominated by the nucleon vector current or by vector meson intermediate states, whereas $\bar{B}^0 \rightarrow D^0p\bar{p}$ proceeds predominately via the axial-vector intermediate state $a_1(1260)$. The study of the $N\bar{N}$ invariant mass distribution in general indicates a threshold baryon pair production, that is, a recoil charmed meson accompanied by a low mass baryon pair except that the spectrum of $D^0p\bar{p}$ has a hump at large $p\bar{p}$ invariant mass $m_{p\bar{p}} \sim 3.0$ GeV. The presence of a hump in the $D^0p\bar{p}$ spectrum

[†]The $\bar{B}^0 \rightarrow D^0p\bar{p}$ spectrum is somewhat sensitive to the model for form factors. In the NR SX model, the peak appearing at low $p\bar{p}$ invariant mass ~ 2 GeV is lower than the hump at $m_{p\bar{p}} \sim 3$ GeV. This is inconsistent with experiment [see the data shown Fig. 4(b)].

FIG. 4. The $p\bar{p}$ invariant mass distribution $d\mathcal{B}/dm_{p\bar{p}}$ of (a) $\bar{B}^0 \rightarrow D^{*0} p \bar{p}$ and (b) $\bar{B}^0 \rightarrow D^0 p \bar{p}$. The experimental data for the spectrum of $\bar{B}^0 \rightarrow D^0 p \bar{p}$ are taken from [3].

can be tested by the improved experiment in the future.
